

Name

uEyeDigitalCrop

Programming language and interface

uEye Software Version:	V4.90.3	
uEye SDK	<input checked="" type="checkbox"/> Core SDK (C/C++)	<input type="checkbox"/> .NET SDK (C#)
Platform of exe file:	<input type="checkbox"/> 32bit	<input checked="" type="checkbox"/> 64bit
Development platform:	Visual Studio 2015	
Operating System	<input checked="" type="checkbox"/> Windows	<input type="checkbox"/> Linux

Description

This sample is based on the uEyeImageQueue demo. In the processing part of the image queue thread, you can run different types of crop operations. All these operations are executed digitally based on the images received in the host. The crop operations are not performed in the camera sensor. In contrast to hardware crop functions on the sensor, the software solution also allows odd scaling factors.

The demo shows you how to access and process the image data using C/C++ pointer operations.

The different results for crop operations can be visualized and compared easily.

Digital subsampling

For subsampling (pixel skip) only a subset of the original image data is required. When using a factor of 2 every second pixel gets dropped. Some image content gets lost. Subsampling works pretty fast with only some data copy operations required.

That can be useful for embedded systems when a camera sensor cannot provide subsampling and for CPU processing power limitations small images are required

Digital binning

Binning is merging neighbor pixels. Image data does not get totally lost as it is when using subsampling. However, some image content gets lost when a cluster of pixel is merged in a single pixel.

Some applications require large pixel sizes. The trend of having smaller pixel design in sensors continues. By merging the pixel in software you can enlarge the pixel size in software.

Binning operation require more CPU load compared to subsampling.

- **Average:** Build the mean value of a cluster. That helps reducing noise. The brightness stays the same.
- **Additive:** The values of the pixels are added. Therefore the brightness is increased.
- **H:additive V:average:** Combining the binning method that way is common on sensor hardware. It is nice mix between reducing noise and gaining brightness.

Bayer conversion with 2x scaling

Based on raw Bayer data from a color camera scaling down the image and color conversion can be done in a single step. The quality of doing a Bayer conversion to a color image might not result in high end in color images. But it is quick and efficient way to get a color image at an embedded system without wasting too much CPU power for the Bayer color conversion.

The source code of the many crop functions is spilt for monochrome and color cameras and the different crop effects. The source code snippets required for a customized can cut and paste easily.

	Mono	Color
Subsampling	DoSubSamplingMono	DoSubSamplingColor
Binning	DoBinningMonoAverage DoBinningMonoAdditive DoBinningMonoAdditiveAverage	DoBinningColorAverage DoBinningColorAdditive DoBinningColorAdditiveAverage
Bayer conversion + scaling		CropDoBayerScaling

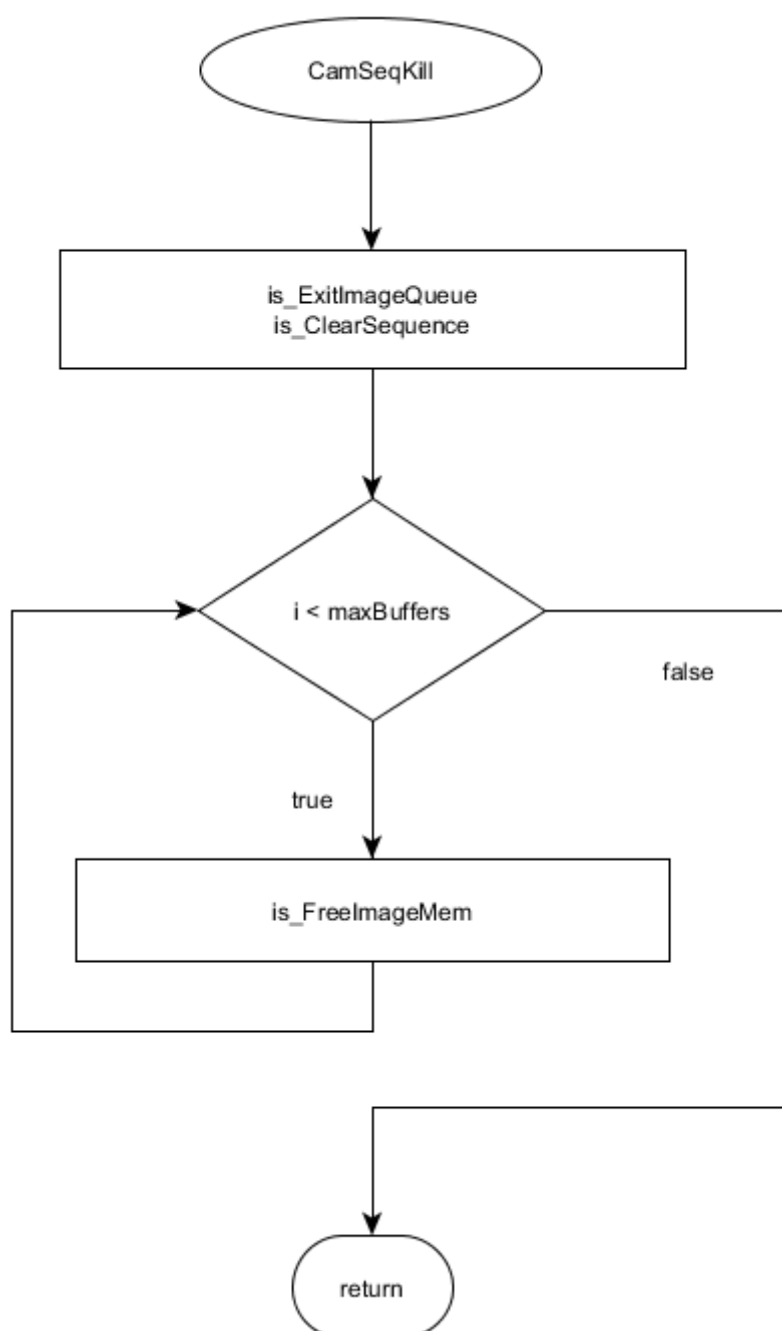

Among others, uEye API functions/methods used

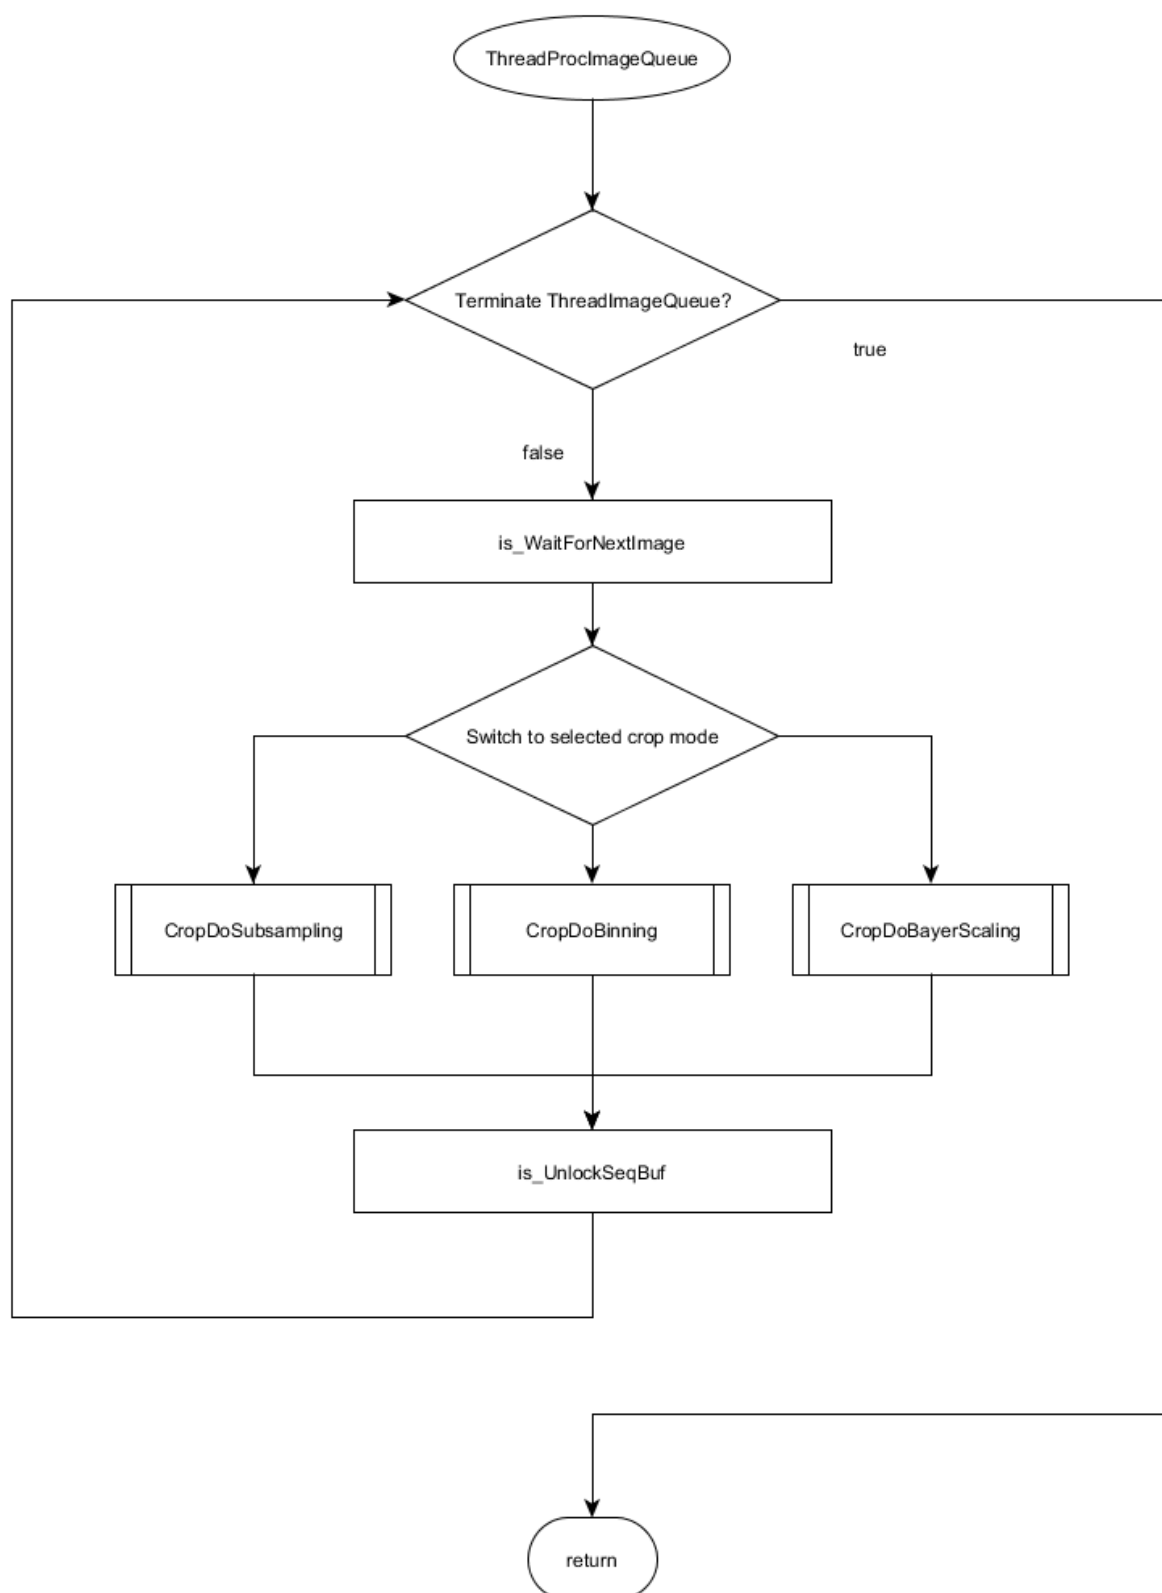

```
is_InitCamera  
is_ExitCamera  
  
is_GetSensorInfo  
is_GetCameraInfo  
is_GetDuration  
is_SetErrorReport  
is_GetFrameTimeRange  
is_SetExternalTrigger  
  
is_AllocImageMem  
is_FreeImageMem  
is_AddToSequence  
is_ClearSequence  
is_GetImageMemPitch  
is_UnlockSeqBuf  
  
is_InitImageQueue  
is_ExitImageQueue  
is_WaitForNextImage  
  
is_FreezeVideo  
is_CaptureVideo  
is_StopLiveVideo  
  
is_SetDisplayMode  
is_SetColorMode  
is_RenderBitmap
```

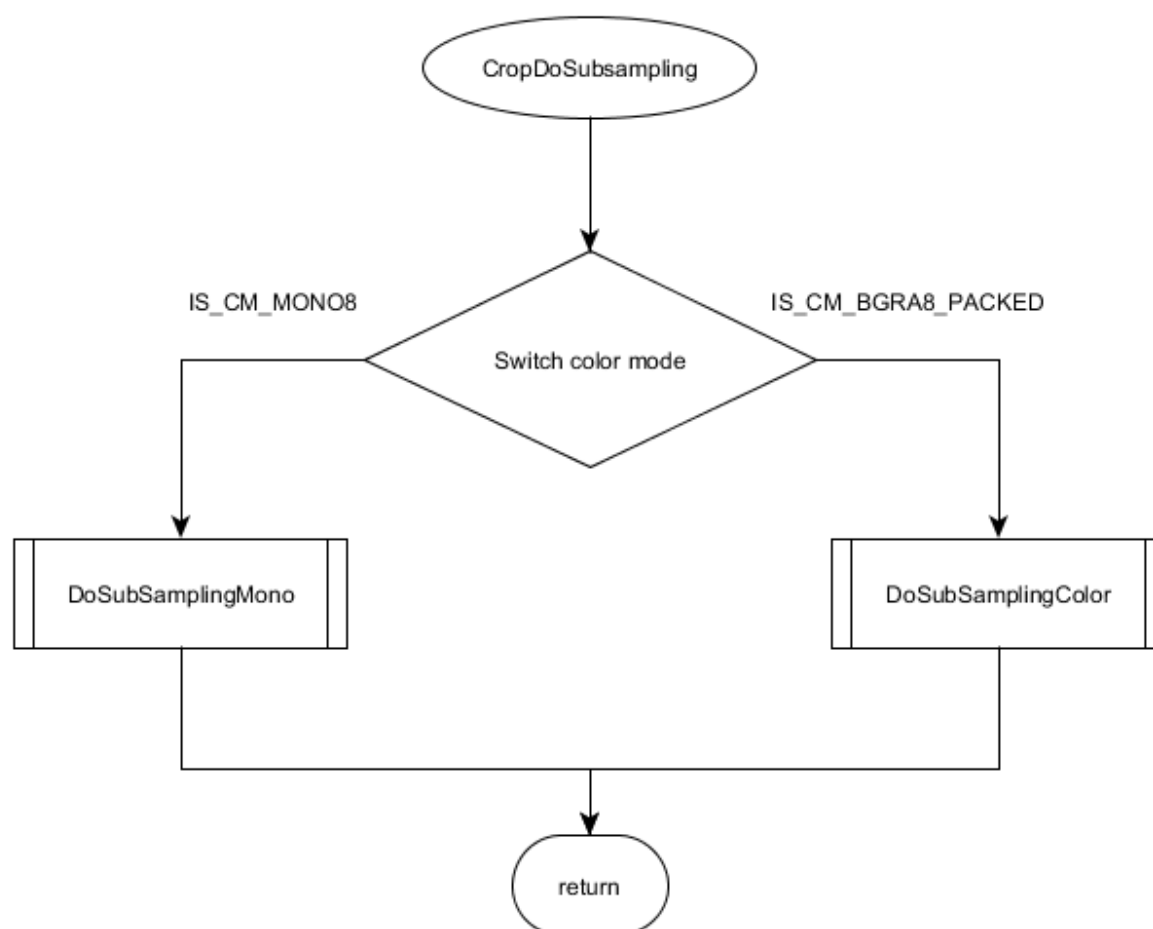

Flowcharts

The flowcharts below show how the most interesting and major parts of the sample software work. The flowcharts do not cover the whole application and all details.

Cameras

All uEye camera models. Note that XS and UI-3013XC camera might require an extra handling.
